

NAME

`init` – process control initialization

SYNOPSIS

`/etc/init`

DESCRIPTION

Init is invoked inside UNIX as the last step in the boot procedure. Generally its role is to create a process for each typewriter on which a user may log in.

First, *init* checks to see if the console switches contain 173030. (This number is likely to vary between systems.) If so, the console typewriter `/dev/tty8` is opened for reading and writing and the Shell is invoked immediately. This feature is used to bring up a single-user system. When the system is brought up in this way, the *getty* and *login* routines mentioned below and described elsewhere are not used. If the Shell terminates, *init* starts over looking for the console switch setting.

Otherwise, *init* invokes a Shell, with input taken from the file `/etc/rc`. This command file performs housekeeping like removing temporary files, mounting file systems, and starting daemons.

Then *init* reads the file `/etc/ttys` and forks several times to create a process for each typewriter specified in the file. Each of these processes opens the appropriate typewriter for reading and writing. These channels thus receive file descriptors 0 and 1, the standard input and output. Opening the typewriter will usually involve a delay, since the *open* is not completed until someone is dialed up and carrier established on the channel. Then the process executes the program specified by its line in *ttys*; the only program currently specifiable is `/etc/getty` (q.v.). *Getty* reads the user's name and invokes *login* (q.v.) to log in the user and execute the Shell.

Ultimately the Shell will terminate because of an end-of-file either typed explicitly or generated as a result of hanging up. The main path of *init*, which has been waiting for such an event, wakes up and removes the appropriate entry from the file *utmp*, which records current users, and makes an entry in `/usr/adm/wtmp`, which maintains a history of logins and logouts. Then the appropriate typewriter is reopened and *getty* is reinvoked.

Init catches the *hangup* signal (signal #1) and interprets it to mean that the switches should be examined as in a reboot: if they indicate a multi-user system, the `/etc/ttys` file is read again. The Shell process on each line which used to be active in *ttys* but is no longer there is terminated; a new process is created for each added line; lines unchanged in the file are undisturbed. Thus it is possible to drop or add phone lines without rebooting the system by changing the *ttys* file and sending a *hangup* signal to the *init* process: use “kill -1 1.”

FILES

`/dev/tty?`, `/etc/utmp`, `/usr/adm/wtmp`, `/etc/ttys`, `/etc/rc`

SEE ALSO

`login` (I), `kill` (I), `sh` (I), `ttys` (V), `getty` (VIII)
