NAME

    init − process control initialization

SYNOPSIS

    /etc/init

DESCRIPTION

    Init is invoked inside UNIX as the last step in the boot procedure. Generally its role is to create a process for each typewriter on which a user may log in.

    First, *init* checks to see if the console switches contain 173030. (This number is likely to vary between systems.) If so, the console typewriter **/dev/tty8** is opened for reading and writing and the Shell is invoked immediately. This feature is used to bring up a single-user system. When the system is brought up in this way, the *getty* and *login* routines mentioned below and described elsewhere are not used. If the Shell terminates, *init* starts over looking for the console switch setting.

    Otherwise, *init* invokes a Shell, with input taken from the file */etc/rc.* This command file performs housekeeping like removing temporary files, mounting file systems, and starting daemons.

    Then *init* reads the file */etc/ttys* and forks several times to create a process for each typewriter specified in the file. Each of these processes opens the appropriate typewriter for reading and writing. These channels thus receive file descriptors 0 and 1, the standard input and output. Opening the typewriter will usually involve a delay, since the *open* is not completed until someone is dialed up and carrier established on the channel. Then the process executes the program specified by its line in *ttys;* the only program currently specifiable is */etc/getty* (q.v.). *Getty* reads the user's name and invokes *login* (q.v.) to log in the user and execute the Shell.

    Ultimately the Shell will terminate because of an end-of-file either typed explicitly or generated as a result of hanging up. The main path of *init*, which has been waiting for such an event, wakes up and removes the appropriate entry from the file *utmp*, which records current users, and makes an entry in */usr/adm/wtmp*, which maintains a history of logins and logouts. Then the appropriate typewriter is reopened and *getty* is reinvoked.

    Init catches the *hangup* signal (signal #1) and interprets it to mean that the switches should be examined as in a reboot: if they indicate a multi-user system, the */etc/ttys* file is read again. The Shell process on each line which used to be active in *ttys* but is no longer there is terminated; a new process is created for each added line; lines unchanged in the file are undisturbed. Thus it is possible to drop or add phone lines without rebooting the system by changing the *ttys* file and sending a *hangup* signal to the *init* process: use ''kill −1 1.''

FILES

    /dev/tty?, /etc/utmp, /usr/adm/wtmp, /etc/ttys, /etc/rc
